 - d. Description of application domain
 - i. Stock Market data analysis system where users will be able to query the information of a certain stock and its prices depending on the given parameters such as high/low prices or on certain dates. The stocks are also able to provide information regarding the company such as its location and number of employees. Stock data is massive due to its long history.
 - e. <https://github.com/GaryQian/Omnicorp>
2. For our project, we will be using financial stock data with its high/low prices as well as adjusted prices to populate the data. Additional data includes the volume of the stock on each day as well as split and dividend information. The data comes from various files some with the prices and others with information related to the company of that stock. With this information, we can query for specific stocks meeting a certain price range or stock values within a date range. Certain calculations can also be queried. Our system allows full access to all stock data dating back almost a century. Due to the large domain, came up with a fragmentation system to greatly improve query speeds.
3. Source of Data
 - a. <https://www.quandl.com/data/EOD-End-of-Day-US-Stock-Prices>
 - b. The dataset was provided through .csv files which we parsed and extracted the financial data through a python script. The data was fragmented across multiple tables with each row storing a shard of the data for the stock on a given day.
 - c. Metadata of companies was manually curated for a subset of the companies to provide supplementary info regarding location, CEO, employee count and more.
4. Running the code:
 - a. To generate the SQL, the user can run the parse.py which will take an argument which will populate the database up to what the user specifies. For example, to prevent exceeding the storage limit, we test with 1,000,000 data inserts. Make sure to download the data, which is 1.7 GB. Note: Since we dealt with big data, the data insertion and preprocessing steps can take significant amounts of time. Our shard of 1,000,000 csv rows took 6hrs to insert using the mysql command line. This can be improved if there is no buffer to print to.
 - b. Start the apache server

- c. Open up Home.html and enter the values to the appropriate field
- 5. We specialize in data-mining and extraction of real data from online sources. The financial data is stock data over the course of all time for every stock listed on the NASDAQ and NYSE. This dataset is massive which requires an efficient system to parse and load into the database within a reasonable time limit. Our queries allow penetration to extract highly specific information rapidly. To make these queries efficient, we fragment the data across multiple tables to reduce tuple size, disk IO, memory usage, and increase efficiency
- 6. Selling Points
 - a. Full access to vast amounts of data
 - b. Vertical Fragmentation across multiple tables to reduce tuple size which means faster joins and lower memory usage.
 - c. Intermediate access to SQL insertion
 - d. Rapid updatability - able to add new data on easily and will stay up to date with stock trends by simply appending to current dataset.
- 7. Limitations
 - a. Due to fragmenting the data, the database requires more storage for storing all the keys redundantly. This adds extra storage overhead as well as requiring multiple insertions of the same data into the database.

8. DB Tables

```
a. drop table Prices;
create table Prices (
    tick    VARCHAR(5),
    date    VARCHAR(10),
    open    FLOAT,
    close   FLOAT,
    high    FLOAT,
    low     FLOAT
);
```

```
drop table Volume;
create table Volume (
    tick    VARCHAR(5),
    date    VARCHAR(10),
    volume  FLOAT,
    adjvolume FLOAT
);
```

```
drop table Misc;
create table Misc (
    tick    VARCHAR(5),
    date    VARCHAR(10),
    divi    FLOAT,
    splitratio FLOAT
```

```
);
```

```
drop table AdjPrices;
```

```
create table AdjPrices (  
    tick    VARCHAR(5),  
    date    VARCHAR(10),  
    aopen   FLOAT,  
    aclose  FLOAT,  
    ahigh   FLOAT,  
    alow    FLOAT  
);
```

```
drop table Company;
```

```
create table Company (  
    tick    VARCHAR(5),  
    name    VARCHAR(25),  
    hqkey   VARCHAR(10),  
    employees INTEGER,  
    CEO     VARCHAR(20),  
    founddate VARCHAR(10)  
);
```

```
drop table Location;
```

```
create table Location (  
    hqkey   VARCHAR(10),  
    city    VARCHAR(15),  
    state   VARCHAR(10),  
    country VARCHAR(10)  
);
```
